Graphene quantum dots (GQDs) are graphene nanoparticles with a size less than 100 nm. Due to their exceptional properties such as low toxicity, stable photoluminescence, chemical
stability and pronounced quantum confinement effect, GQDs are considered as a novel material for biological, opto-electronics, energy and environmental applications.

**Graphene quantum dot - Wikipedia**
Graphene quantum dots (GQDs) that are flat 0D nanomaterials have attracted increasing interest because of their exceptional chemicophysical properties and novel applications in energy conversion and storage, electro/photo/chemical catalysis, flexible devices, sensing, display, imaging, and theranostics.

Graphene quantum dots (GQDs) are nanoscale structures of graphene having strong quantum property and edge effects resulting in exceptional photoluminescence properties. The quantum confinement effect and different nature and density of sp² sites in the structure of GQDs make their optical characteristics critically dependent on their structure size.

**Graphene Quantum Dot - an overview | ScienceDirect Topics**
Graphene quantum dots (GQDs), which constitute a zero-dimensional photoluminescence (PL) carbon-based nanomaterial consisting of very thin (typically 3–20 nm) graphene sheets that exhibit exciton confinement and quantum-size effect, recently aroused much scientific interest by virtue of their exceptional properties.

Pristine graphene quantum dots and graphene oxide quantum dots are synthesized by chemical exfoliation from the graphite nanoparticles with high uniformity in terms of shape (circle), size (less than 4 nm), and thickness (monolayer). The origin of the blue and green photoluminescence of GQDs and GOQDs is attributed to intrinsic and extrinsic energy states, respectively.

Quantum dots. Nanoparticles of semiconductors (quantum dots) were theorized in the 1970s and initially created in the early 1980s. If semiconductor particles are made small enough, quantum effects come into play, which limit the energies at which electrons and holes (the absence of an electron) can exist in the particles.

Carbon and graphene quantum dots (CQDs and GQDs), known as zero-dimensional (0D) nanomaterials, have been attracting increasing attention in sensing and bioimaging. Their unique electronic, fluorescent, photoluminescent, chemiluminescent, and electrochemiluminescent properties are what gives them potential in sensing.

2.2. Preparation of graphene quantum dots. GQDs were prepared through two step reactions. First, GO was prepared from graphite powder according to the Hummer method with minor modification[]. In the typical experiment, 4 g graphite powder and 3 g NaNO 3 were dispersed into 150 ml concentrated H 2 SO 4 under ice bath, then 18 g KMnO 4 was slowly added into the mixture with vigorous vortex.
